The use of motion detectors for monitoring the location of an individual has become prevalent. This practice is sometimes adopted by individuals who may be in homes with others, by parents who wish to monitor the whereabouts of children, and even by employers who wish to monitor the whereabouts of employees to discover where they may be at times when they are not supposed to be working. Other uses for such monitoring may arise as well. There are a number of different types of motion detectors that have been developed. These devices can be broadly classified as being either passive or active. Passive devices are those which produce no sound of any kind and do not rely on the use of energy or electricity, as is the case with active devices. Passive motion detectors respond to movement in their immediate vicinity and produce a disturbance of some type. For example, a strong magnetic field can be produced in the vicinity of the motion detector, which is sensed by a magnetic detector. If the magnetic field is interrupted by movement, a signal is produced to alert the person as to the presence of a moving object. Passive detectors do not rely on a power source and are quite simple in operation. Active devices, on the other hand, produce sound or electric impulses of some type, which can alert the user to the presence of an object. Active devices are generally more complicated than passive devices. Some sensors produce sound in the form of a high frequency pulse which can be detected by a microphone and converted into a more audible sound. These devices generally require a power source, such as a battery. In the past, passive devices were used to detect the presence of sound. However, these devices could only detect the presence of sound. Such a device could be used to alert a person to the presence of something like a human intruder, but not in a manufacturing plant or other areas where relatively low noise levels may occur. More recently, active devices have been developed to detect the presence of sound. The user may at a predetermined time or in response to an activation signal produce a constant sound that may be detected by a microphone, which produces a signal in response thereto. The signal may then be demodulated into audio which may be heard by the user. For example, a user may be instructed to produce a whistle or an alarm of some type at predetermined times. Upon the occurrence of the sound, the user is alerted to the existence of the sound and may take appropriate action in response thereto. Active devices are superior to passive devices because they are able to detect the presence of actual sound. Thus

Q: How to store data at a given location in memory Say I have the following code, `public class SomeClass { private int[] data; public void addData() { data = new int[2]; data[0] = 1; data[1] = 2; } }` This is just an example, assume that it's a big complex class with lots of methods. Now if I store the data into the array, there is a possibility that it will be out of scope. What is a good way to store this array of values in such a way that: When calling `addData()` a new instance of the array is created When using this array the values are still in memory at the same address. I'm not looking for the answer to this specific question, but rather I'm looking for a general idea on how to organize my data in such a way that the data isn't out of scope and that the data is still in memory at the same address. A: The basic answer is that this is not possible. In your example, `data` is a field, and you create an array. I don't see any reason why it's out of scope. For example, a bank has a single account. On creation, it's open. If you try to withdraw from it, you will find you're not able to. In this case, if you make it a local variable in a method, it is guaranteed to exist for the entirety of the method and it's safe. If you're trying to store a large amount of data such as an array of integers, etc., it's probably a bad idea to do it this way. You probably want to instead look at using a database such as SQLite, MySQL or PostgreSQL. While you could create your own database using memory, that would end up using a lot of memory and locking a lot of stuff so would be a terrible idea. Sneakers and boots are coming soon to the city.
