There are several well-known data structures in the form of a binary heap or a binary search tree, which can be used to implement a priority queue, but there are several algorithms that achieve better locality than a binary heap, and over the years data structures such as a linear list, linked lists, and priority queues were developed for use in this class of data structures. A combination of these algorithms forms a binary heap or its complement, a b-heap. In 1973, James F. Jackson and Herbert T. Kung published an analysis showing that, using a specific selection of algorithms, the binary heap could be made almost as efficient as the binary search tree. The theoretical analysis was formalized into a simple algorithm called LEMMA (), which is also used in practice in several different data structures, such as the AVL tree. Since the publication of Jackson and Kung's analysis, heaps have become the default data structure for priority queues. Description. Maple 13 : A student edition of Maple with all the tools needed to create advanced 2D and 3D models. It allows the creation of geometric diagrams with corresponding properties. The relationship between the graph's geometric properties and its mathematical properties is very important in many areas of engineering design. Maple 13 is a powerful modeling environment for creating numerous graphs and mathematical models of all shapes and levels of complexity.
